Cooperating with

National Agricultural Statistics Service

ACKNOWLEDGMENT

The inventory data contained in this report were developed at the request of and with funds provided by Florida's Citrus Industry. Its leaders sought accurate information for projecting future production and recognized the requirement to maintain citrus tree and acreage inventories on a current basis.

The work was directed by the Florida Agricultural Statistics Service which supervised photography, photo interpretation, field checking, and assembly of the data. Field survey work was a continuing cooperative project of the Florida Agricultural Statistics Service and the Division of Plant Industry.

Private and public officials contributed to this work by supplying information and other assistance. Many growers supplied basic data. These contributions are sincerely appreciated.

SURVEY HIGHLIGHTS

Commercial citrus acreage in Florida declined to 748,555 from 797,303 in 2002. A net decrease of 48,748 acres has occurred in the past two years. Plantings during 2002 and 2003 totaled 40,127 acres, but removals totaled 88,875, the largest amount in a non-freeze survey period. Tree counts decreased from 103,172.0 in 2002 to the current 97,945.0 tree total for 2004.

Polk County is the leader with 95,050 acres of citrus, followed by Hendry with 93,155 and St. Lucie with 82,987. Hendry County continues to lead in total trees and averages 153 trees per acre, 22 more than the state average. Following in total tree numbers are Polk with a density of 117 trees per acre and St. Lucie County with an average of 125. Acreage increased in 3 of the 31 citrus counties during the past two years. Miami-Dade County is excluded from this publication.

2002	648,806	105,488	43,009	797,303
2004	622,821	89,048	36,686	748,555

The total tree inventory by year set as indicated in the censuses of 1986 to 2004 is shown on page 109. The 2004 census indicates that only 196,404 acres (31.5 percent) remain from the 624,492 reported in the 1986 census.

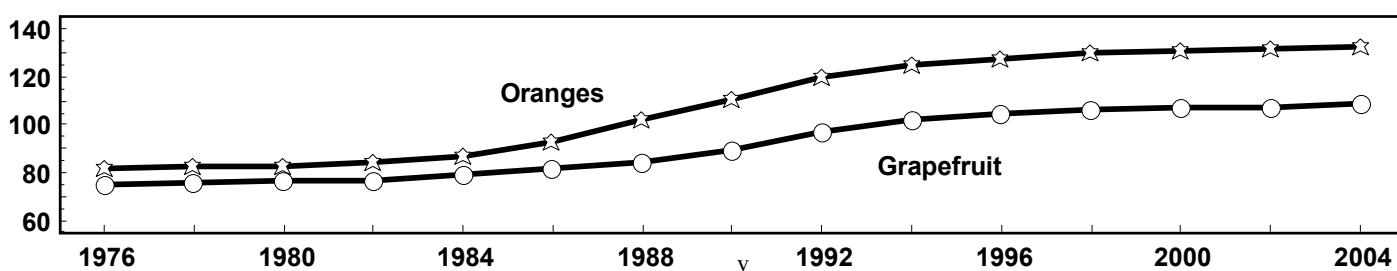

The gross acreage decline in the past two years is 11.1 percent of the 2002 inventory. Gross loss of oranges amounted to 9.3 percent while grapefruit recorded a loss of 20.0 percent. Specialty fruit had slight acreage gains in Minneola tangelos, other tangelos, and true lemons; but losses in Temples; Fallglo, Sunburst, and Honey tangerines; and those fruit types now comprising the "Other Citrus" category.

Commercial Citrus Trees per Acre

SURVEY PROCEDURES

This publication presents the results of the 20th biennial survey of Florida citrus trees using aerial photography. Aerial photography and photo interpretation provide for more rapid completion of the survey than other methods; still about eight months of intensive effort is required to process and review the photographs. Grove changes are detected by comparative photo interpretation, followed by field checking of new and altered acreage. Changes disclosed on photographs and in field observations are used to update the previous inventory. This technology provides current tree inventory data for evaluating Florida's potential citrus production in a shorter period of time and at less cost than by ground survey methods alone.

The data in this report relate to commercial groves, those containing a minimum of 50 trees from which fruit is generally sold. In addition, the grove must have been cultivated and trees must show viable growth in the limb scaffold. Variety totals were rounded to the nearest acre and one hundred trees. All item totals that fell below these parameters were listed as zero. For this reason, users are cautioned that zero cells in the data tables could actually have a positive entry, but would be less than one half acre and below 50 trees.

The acreage shown is land which is actually planted with citrus trees. Bayheads, ponds, sinkholes, drainage canals, lateral and swale ditches, roads, turn rows, and wide middles were excluded. Where vacancies within a commercial grove were numerous, they were counted and acreage was then reduced to equivalent net acres of commercial trees. Trees are listed by the calendar "year in which set," even if they have been severely pruned. When available, grove managers' records were used to establish age. Young tree age was estimated from both trunk circumference and tree height.

Identification of citrus varieties generally depends on the presence of fruit. Many young groves visited for the first time are indexed as unidentified until fruit is available for variety determination. Acreage and trees in this report listed as "unidentified" will be resurveyed and classified by variety in the next census. The unidentified trees and acres are listed by year set and by county under all Florida citrus. They are also included in the all orange and all grapefruit totals.

Data itemized under the heading of other citrus include minor types and varieties, such as limes, Ortaniques, Ponkans, Satsumas, unidentified mandarins, K-Early Citrus, unclassified citrus, kumquats, and pummelos. They are not reported individually or by year set within county due to lack of space.

The Florida Agricultural Statistics Service first began indexing citrus groves on aerial photography with the January 1966 survey. The 1966 inventory report included detailed data by county, variety, and year set; and the survey was designed for quick and economical updating. Subsequent surveys, using aerial photography, were conducted as of January every two years including the latest for 2004.

The same three-mile wide flight lines established for the January 1966 survey were photographed on each of the succeeding flights. Some additional coverage has been added as citrus acreage has extended farther south. The area, photographed at a scale of 1 inch to 2,500 feet, now covers almost 14,000 square miles and includes more than 99

percent of the commercial citrus acreage in Florida. Photographing for the latest survey began the first of December 2003 and was completed by the end of January 2004.

Since it is not economically feasible to photograph the few hundred scattered acres of outlying citrus, supplemental photography has been purchased, where available. In the absence of photography, the outlying acreage was mapped and thoroughly checked by ground survey teams.

Stereoscopic viewers enabled interpreters to examine current and previous photo contact prints simultaneously to detect changes occurring during 2002 and 2003. Altered ground characteristics result in a loss of the three-dimensional effect, making such changes as new groves, additions to existing groves, pushed groves, and other significant alterations quickly identifiable. The photo interpreters identify all groves where there appear to be new trees. These groves are then visited by ground crews. If field inspection finds a significant number of new trees, a count is made and the older trees or vacancies reduced accordingly. Based on this new count of trees, the measured block acreage is then divided among the ages of trees.

In December 2003, field crews began ground checking sites that had been questioned by photo interpreters on the new photography. All blocks showing changes since the 2002 flight were visited. Crews also identified varieties in blocks where trees were too young to be identified in earlier surveys. In blocks of citrus which are interset, acreage is proportionate to the number of trees of each variety or age in the block. In the multi-reset blocks, two or more resets are planted for each tree removed. The spacing must be averaged due to the variable distance between trees. The spacing between rows in one direction remains constant for grove travel.

Field work was completed the second week of July. Following field inspection, photo interpreters delineated and indexed all new citrus groves and grove changes by variety blocks on cronaflex enlargements of aerial photographs. Digital planimeters were used to measure acres of new and altered citrus groves. Acres were computed from the combination of tree numbers and tree spacings as measured by field personnel. All statistical information (variety, year set, acreage, tree numbers, and identifying features) was then keyed into a data base and retained for future use. There are 162,575 data records identifying all variety blocks, which were summarized by computer and retained in electronic media for future updating.

A light table is used to visually compare replacement cronaflex enlargements with the previous master transparencies on which groves are delineated. Questionable observations are noted for verification by field inspection. Resurveying is a continuing process between flights. Quality checks for accurate variety counts will be emphasized as well as the identification of the three year old plantings that are to be included in next year's objective count surveys. Also, all groves that had vacancies this past survey will be visited prior to the 2006 flight.

The Division of Plant Industry supplied trained citrus technologists with 4-wheel drive vehicles to work on the tree census field inspection team. Assistance was also provided by personnel from the Division of Fruit and Vegetables.
