Acknowledgement

The acreage, production, utilization, monthly and season price, and crop value statistics for Florida as shown in this summary and corresponding data for other citrus states are official estimates of the USDA's National Agricultural Statistics Service. Chilled and frozen pack statistics were compiled by the Florida Department of Citrus. Where data are from other sources, appropriate references appear. Records of the Division of Fruit and Vegetables, Florida Department of Agriculture and Consumer Services, were used in preparing production and utilization estimates. The Citrus Administrative Committee assisted in assembling these data. Many producers, shippers, processors, sales agencies, transportation firms, and others associated with the citrus industry voluntarily supplied basic data used to develop these statistics. Their contributions are sincerely appreciated.

The inventory data contained in this report were developed at the request of and with funds provided by Florida's citrus industry. Its leaders sought accurate information for projecting future production and recognized the requirement to maintain current citrus tree and acreage inventories. The work was directed by the Florida Agricultural Statistics Service which supervised photo interpretation, field checking, and assembly of the data. Field survey work is a continuing cooperative project of the Florida Agricultural Statistics Service and the Division of Plant Industry. Private and public officials contributed to this work by supplying information and other assistance.

Florida Citrus Pricing, Packout Rates and Sample Calculation of Grower's Return Prices

All prices reported in this publication, except the prices in the table on page 11, are on-tree prices representing the average price received by growers for their fruit. The term "on-tree" relates to fruit returns to the grower after the costs of picking, hauling, and packing has been removed. Prices are based on records of commercial fresh fruit sales and processed fruit returns.

Each season, beginning with the first month that at least 3 percent of a fruit type is harvested, monthly estimates are computed. Reports from fresh fruit sales organizations and from packers provide data for an average freight-on board (f.o.b.) price. Processors report an average spot and cash price for fruit delivered to their plants. From these values, an estimated charge for picking, hauling, and packing is deducted to arrive at an on-tree price. The anticipated box utilization for the month is used to combine the fresh and processing price to obtain an average price for all methods of sales.

At the season's end, monthly price averages are computed and weighted by boxes utilized to provide the preliminary season average price. A year later, after most processed products are sold, cooperatives and firms with participation plans report prices of fruit they handled. These prices, combined with the spot and cash prices collected earlier, are weighted together by varieties to determine the final processing price received by growers. From this price, charges for picking, hauling, and packing, as estimated by University of Florida economists, are deducted to arrive at the final on-tree price received by growers. The preliminary figures for the season are revised and released annually in late September.

Packout Rates

Fresh prices shown in this publication are for "pure fresh" or 100% packout. Grading diverts a portion of the crop from fresh use. Returns at processing plants for this diverted fruit will generally be less than for field run fruit because of extra costs. In order to compare fresh prices shown in this publication to the individual grower's return it is necessary to calculate a derived price for that crop. Below is an example and a blank table for calculating fresh returns based on packout rates.

The example describes a delivery of 1,000 boxes with a packout rate of 60% (0.60 in decimal format). At this rate, 600 boxes (1,000 x 0.60) are shipped fresh at a price of \$9.50 per 1 3/5 bushel box equivalent. The remaining 400 boxes (1,000 x 0.40) are eliminations hauled to a processing facility and receive a price of \$1.20. The grower receives \$5,700.00 for the fresh portion and \$480.00 for the processed portion. Dividing the total amount of \$6,180.00 by the total of 1,000 boxes results in a derived price of \$6.18 per box.

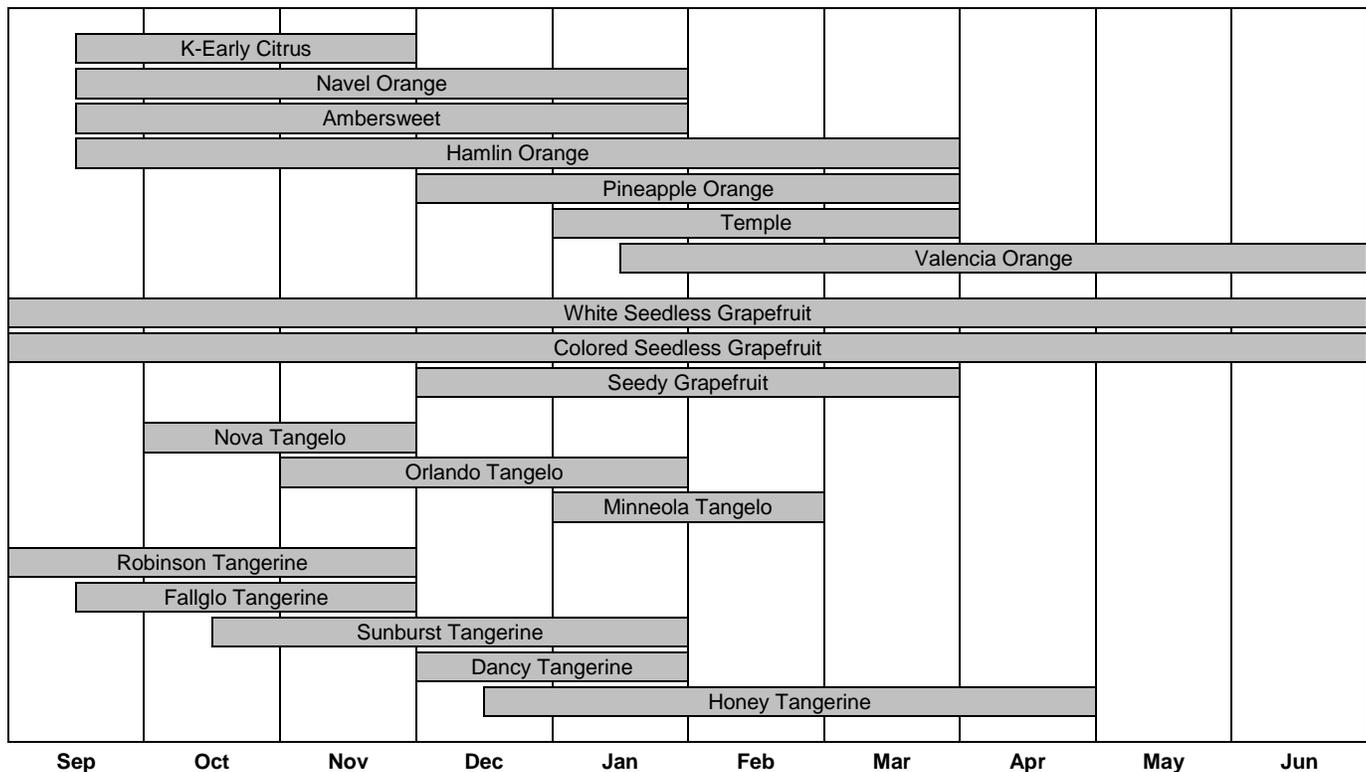

Sample Calculation of Grower's Return

	Packout Rate		Prorated Boxes	On-tree Price	Amount Received	Derived Price
	Percent	Decimal				
Shipped Fresh	60	0.60	600 x Fresh	\$9.50 =	\$5,700.00	
Eliminations	40	0.40	400 x Processed	\$1.20 =	\$480.00	
Delivered to Packinghouse	100	1.00	1,000		\$6,180.00	\$6.18

Calculate Your Return

	Packout Rate		Prorated Boxes	On-tree Price	Amount Received	Derived Price
	Percent	Decimal				
Shipped Fresh			x Fresh	=		
Eliminations			x Processed	=		
Delivered to Packinghouse						

FLORIDA CITRUS HARVESTING SEASON

2009-2010 Season Highlights

Production

Citrus utilized production for the 2009-2010 season in the United States totaled 10.9 million tons, down 8 percent from the 2008-09 season. Florida accounted for 65 percent of the total United States citrus production with 159.3 million boxes of citrus in the 2009-2010 season, California totaled 31 percent, and Texas and Arizona produced the remaining 4 percent.

Florida's total 2009-2010 citrus utilization decreased 16 percent from the previous season. Utilized citrus production in California increased 15 percent for the 2009-2010 season. Utilized citrus production in Texas was up 4 percent. Total citrus production in Arizona was down 27 percent from the previous season.

Florida's all orange production fell 18 percent to 133.6 million boxes. Navel production was 2.3 million boxes, down 23 percent from the previous 2 seasons and the lowest since 1985-1986. Grapefruit utilization in Florida, at 20.3 million boxes, was down 6 percent from the 2008-2009 season's utilization. Honey tangerine production at 2.2 million boxes was up 69 percent from last season's 1.3 million boxes, the lowest since 1994-1995.

Area and County Production

Total citrus production in 2009-2010 was down in all Florida commercial citrus production areas from the 2008-2009 season. The Southern and Western areas were down the most with decreases of 13.4 million and 7.4 million boxes respectively. The Northern area decrease of less than 400 thousand boxes was the smallest. The top 5 citrus producing counties were Polk (27.9 million), Highlands (21.6 million), DeSoto (18.0 million), Hendry (16.3 million), and Hardee (13.0 million). Losses were recorded in all counties with the exceptions of Hernando and Orange.

Estimates of county production are prepared from objective survey data used in forecasting citrus crop production. The apportionment of final harvest to the counties is based on bearing trees, an estimate of the average fruit per tree, and the drop and size surveys. Sample size and the distribution of the sample groves around the State used in these surveys are chosen to minimize error in the estimates of production and are not to be considered as accurate for the counties as at the State or area levels.

Value

The value of the 2009-2010 United States citrus crop increased 5 percent from last season, to \$2.88 billion (packinghouse-door equivalent). Even though United States citrus production was lower than last season, higher prices for the majority of the citrus crops pushed crop values up. Orange value of production decreased 2 percent from last season while grapefruit value is up 28 percent. Tangerine and mandarin value of production is 33 percent higher than last season and lemon value of production is up 14 percent. Tangelo value increased 23 percent from the previous season.

Florida's \$1.055 billion (on-tree equivalent) preliminary value of the 2009-2010 citrus crop is 1 percent greater than the revised value of \$1.047 billion for 2008-2009. The price per box was higher for all varieties. White grapefruit and tangelos rebounded from last season's lower prices and on-tree values more than doubled. The all tangerine value increased 73 percent. Only the orange on-tree values are lower.

Foreign Exports

Fresh fruit exports totaled 12.4 million 4/5 bushel cartons. Japan accounted for the majority of Florida grapefruit. Canada received most of Florida's orange and specialty fresh fruit exports. More details are listed on page 45. A total of 16.0 million gallons of Frozen Concentrated Orange Juice (FCOJ), and 4.4 million gallons of Frozen Concentrated Grapefruit Juice (FCGJ) were exported in the 2009-2010 season.

Citrus Value of Sales On-Tree-Florida: Crop Years 2000-2001 through 2009-2010

Crop year ¹	Value (1,000 dollars)	Crop year ¹	Value (1,000 dollars)
2000-2001	862,031	2005-2006	1,024,610
2001-2002	966,803	2006-2007	1,499,112
2002-2003	787,378	2007-2008	1,283,994
2003-2004	891,500	2008-2009 ²	1,046,735
2004-2005	754,169	2009-2010 ³	1,054,716

¹ Excludes lemons beginning in 2003-2004.

² Revised.

³ Preliminary.

Frozen Concentrate

Final Frozen Concentrated Orange Juice (FCOJ) yield, as reported by the Florida Department of Citrus, was 1.559677 gallons per box of 42° Brix concentrate, far below the record of 1.672737 set in the 2007-2008 season. The early-midseason portion of the crop finalized at 1.511083 gallons per box. The late crop yielded 1.625245 gallons per box.

The final Frozen Concentrated Grapefruit Juice (FCGJ) yield was 1.309023 gallons per box of 40° Brix concentrate, up from last season but lower than the 1.31020 gallons per box recorded in 2007-2008.

The final Frozen Concentrated Tangerine Juice (FCTJ) yield of 1.438629 gallons per box of 42° Brix concentrate was lower than last season's final of 1.567257 gallons per box.

Average Delivered-in Processed Price – Florida: Crop Year 2009-2010

[Price for fruit used in concentrate by variety]

Variety	Price per box (dollars)	Price per pound of solids (dollars)
All oranges	8.807104	1.395414
Early-midseason	7.844240	1.300389
Valencia	9.832372	1.487770
All grapefruit	5.533380	1.142646
White	5.516078	1.161954
Colored	5.556241	1.118271

Weather, by Months-Florida: Crop Year 2009-2010

January 2009 began with dry conditions and warm temperatures across the citrus region. Lack of rain continued until the third week of the new year, when a northern cold front with much needed rain passed over the state. Neither the decreased temperatures nor the precipitation lasted long. Dry conditions and warmer weather returned by the end of the month with highs reaching the lower 80s during the day in most citrus producing areas. Towards the end of the first week of February, cold weather was experienced again across the citrus region. This time temperatures dropped to the mid 20s in parts of the southern citrus region. Compounded by windy conditions, the abnormally dry air made irrigation essential. Warmer temperatures again rebounded with daily highs reaching the lower 80s.

March 2009 began with a short cold snap followed by a gradual return to more normal temperatures; however the lack of rain continued. April was warm and dry, and the drought experienced by the citrus region worsened. Relief arrived in mid-May when several days of storms and heavy showers drenched Florida's citrus producing region. A number of areas experienced localized flooding, prompting some growers to pump excess water out of the groves into canals and reservoirs. By the end of the month, the heavy showers tapered off. Typical Florida summer weather patterns returned with quick-moving late afternoon and evening rain showers following days full of sunshine.

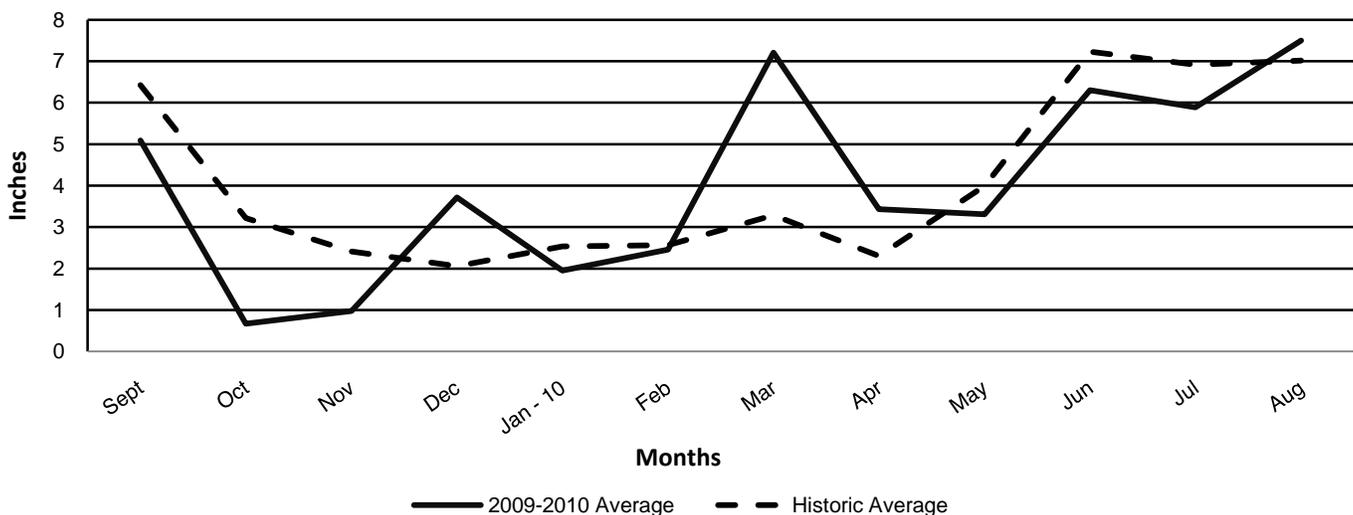

June and July both exhibited normal Florida weather patterns, consisting of warm days into the mid to upper 90s with afternoon thunderstorms and showers most days. Several days of heavy thunderstorms occurred during August. Mostly, weekly rainfall totals were between one and three inches. Rainfall was heavy at the beginning of September but began to taper off by the end of the month; temperatures remained about average.

Drier conditions and seasonal warm temperatures marked October and November. December's increase in rainfall ended the moderate drought that had been in place for much of the year. January 2010 began with several nights of extremely low temperatures, prompting heavy irrigation and increased harvesting. Temperatures returned to a more normal range by mid month, and remained so through February. The entire citrus region remained drought free.

March 2010 brought heavy, soaking rains during the early stages of the bloom, along with normal temperature ranges. Typical temperature and rainfall patterns continued during May and June. Mild drought conditions returned during July to the easternmost portions of the citrus producing area. Although August precipitation was above the 2009-2010 average throughout the citrus producing region, Fort Pierce received 33 percent less than the historical average.

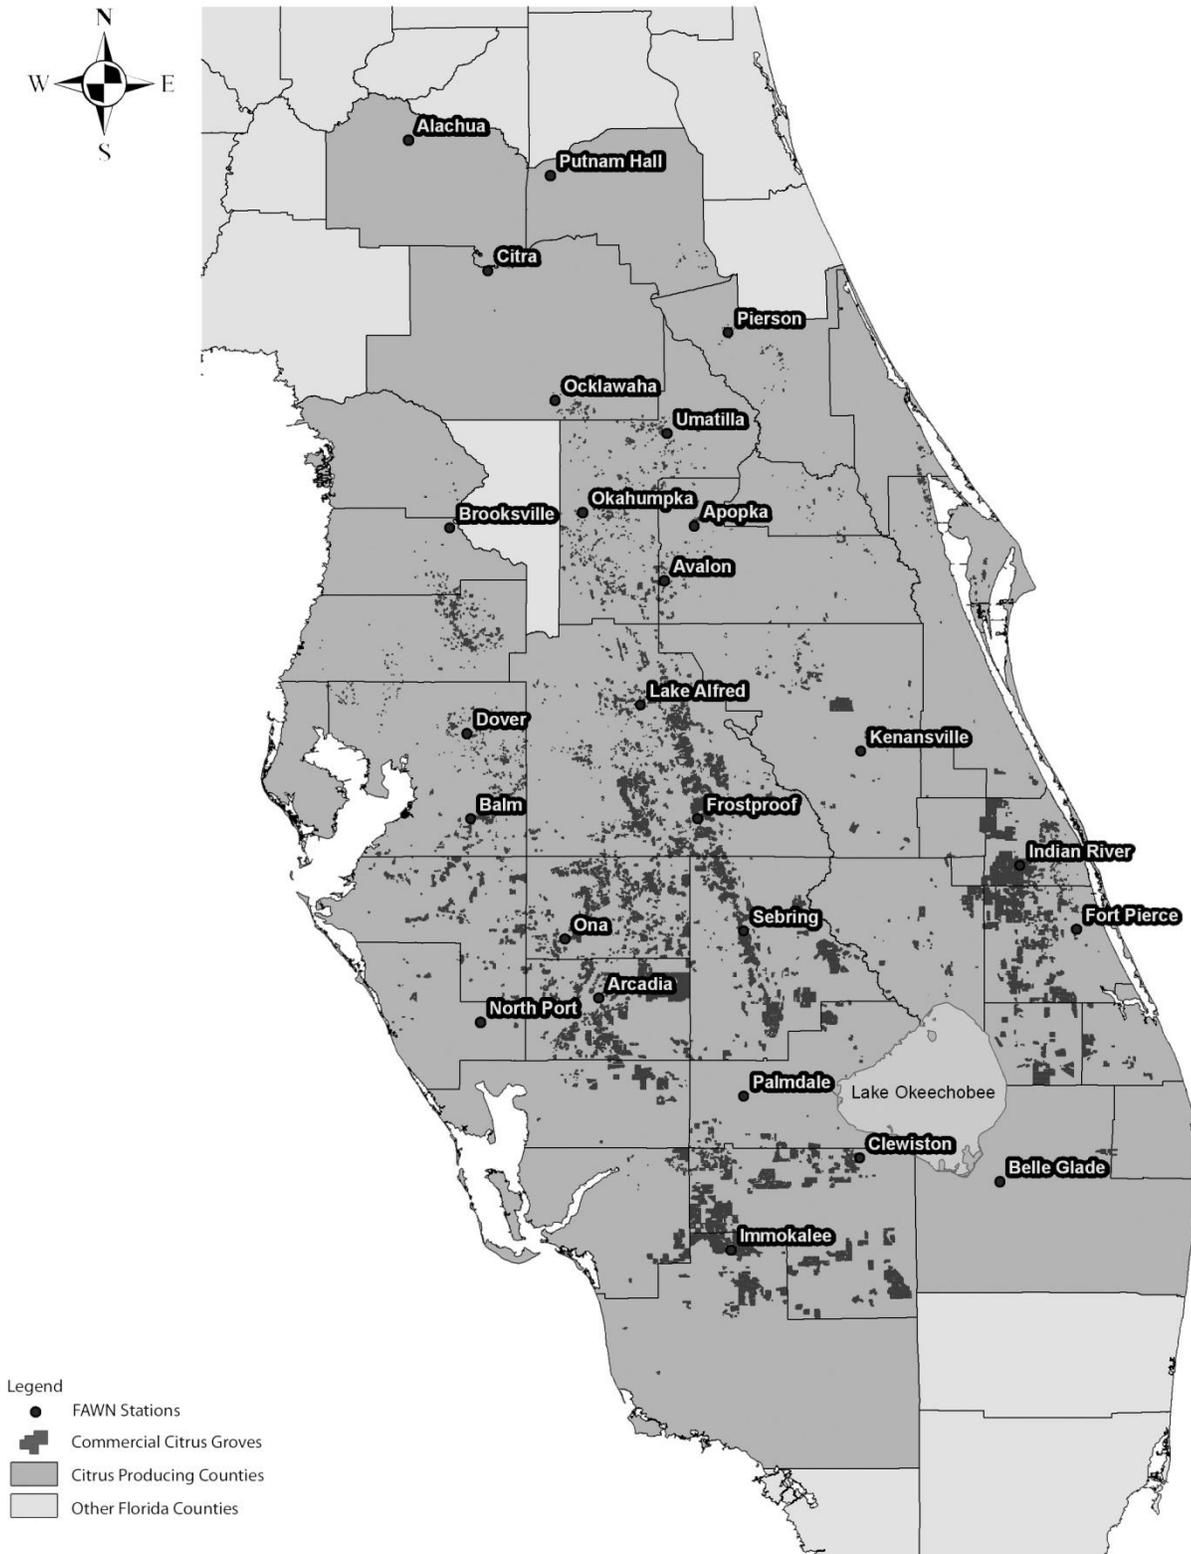

In the chart below, the 2009-2010 monthly rainfall is compared to the historical average data from 10 stations scattered across the citrus producing area. The 10 stations are: Apopka, Arcadia, Balm, Ft. Pierce, Immokalee, Clewiston, Lake Alfred, Sebring, Umatilla, and Kenansville.

History of Florida's Citrus Industry

Citrus is native to the Orient; it was carried westward by man, to India, the Mediterranean, and across the Atlantic. When Columbus landed on Hispaniola in November 22, 1493, on his second voyage, he brought citrus seeds that were planted on the island. The first seeds planted on the mainland of the Americas were brought by the expedition of Juan de Grijalva when he landed in Central America between July 12 and July 20, 1518. The exact date of the introduction of citrus trees into Florida is not known, but from a statement made by Pedro Medendez, dated April 2, 1579, it appears that citrus fruits were grown in abundance around St. Augustine at that time. Early settlers in Florida some two centuries later found wild citrus trees scattered over the State. One of the oldest cultivated groves planted in Florida (Hume, 1926, p. 95) is thought to have been the Don Phillipe grove in Pinellas County, planted sometime between the years of 1809 and 1820. Nearly 1.5 million boxes were shipped in 1887-1888, the first season on record. Citrus production in Florida had reached a high of more than 5 million boxes when the Great Freeze of 1894-1895 nearly wiped out the entire citrus industry. It was not until 1909-1910 that this level was reached again. The highest production ever was reached in the 1997-1998 season, when Florida produced 304.5 million boxes.

¹ Average weighted by bearing trees.

² Hurricane Wilma adversely affected production in the Indian River and Southern areas.

³ Includes Temples beginning in 2006-2007.

The Florida Agricultural Statistics Service conducts objective surveys to determine fruit per tree, average sizes, and droppage between August and maturity. These data are used to estimate production per tree for each of four types of citrus fruit, as shown in the following tables. The estimates of production per tree are based on official end-of-season production estimates and the number of bearing trees indicated by the Commercial Citrus Inventory. The averages of boxes per tree for age groups shown are calculated from estimates of fruit per tree in August, size at maturity, and drop between August and maturity. Additionally, the boxes are subdivided by production areas. Estimated boxes by types and age groups are weighted averages of the indicated seasons. Small sample sizes in some age/area cells and rounding may contribute to inconsistent averages.

Valencia Orange Estimated Boxes of Fruit per Tree, by Age Group by Production Area — Florida: 2005-2006 through 2009-2010

(NA) Not available.

¹ Crop year refers to harvest and marketing period, which usually begins in the fall and extends to the spring.

² One metric ton is equivalent to 2,204.6 pounds.

³ Includes Temples.

⁴ Excludes Bulgaria and Romania in 2005-2006.

⁵ Mozambique, Malaysia, Japan, and Russia.

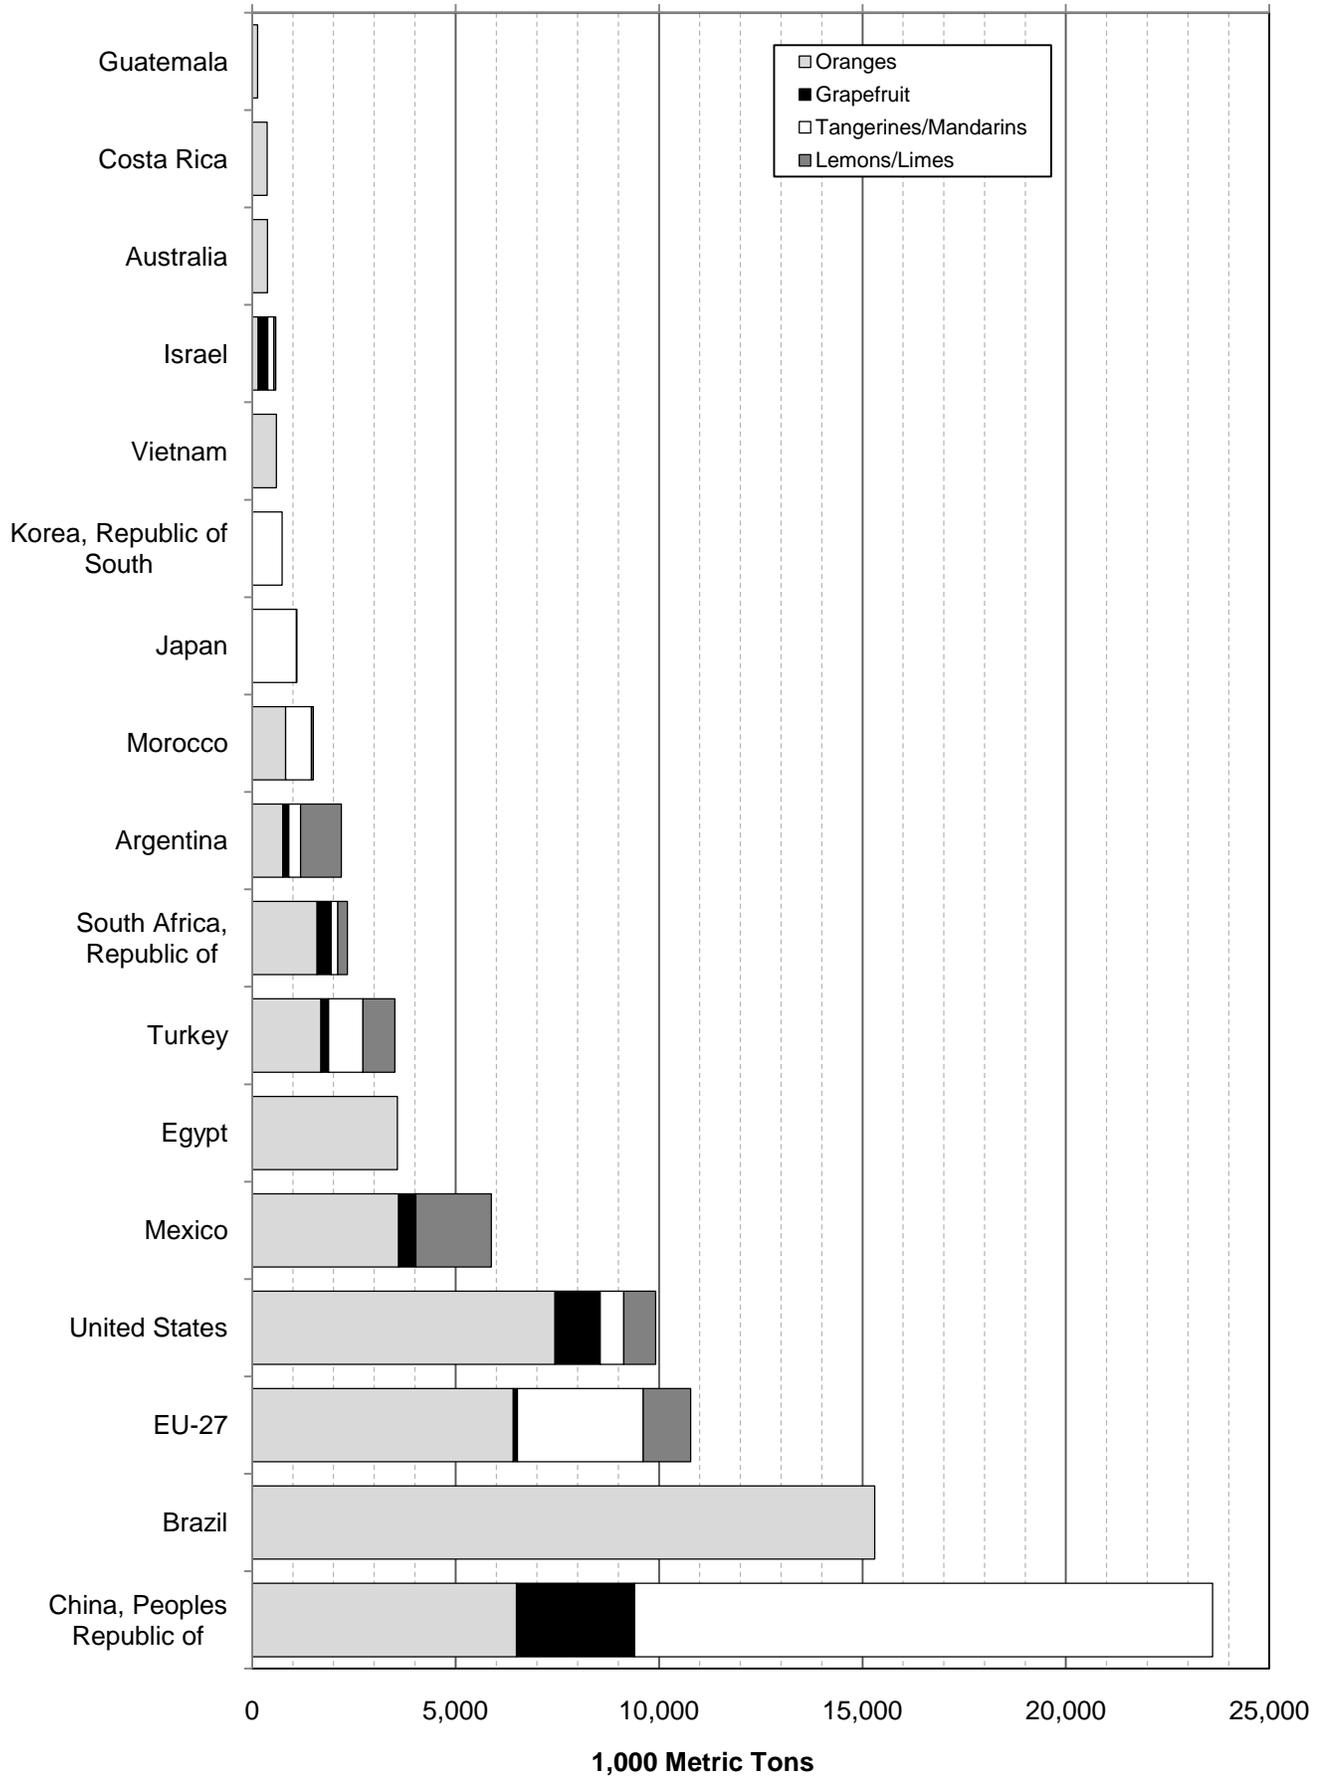

⁶ Mainly Satsumas, but also including mandarin hybrids.

⁷ Clementines only.

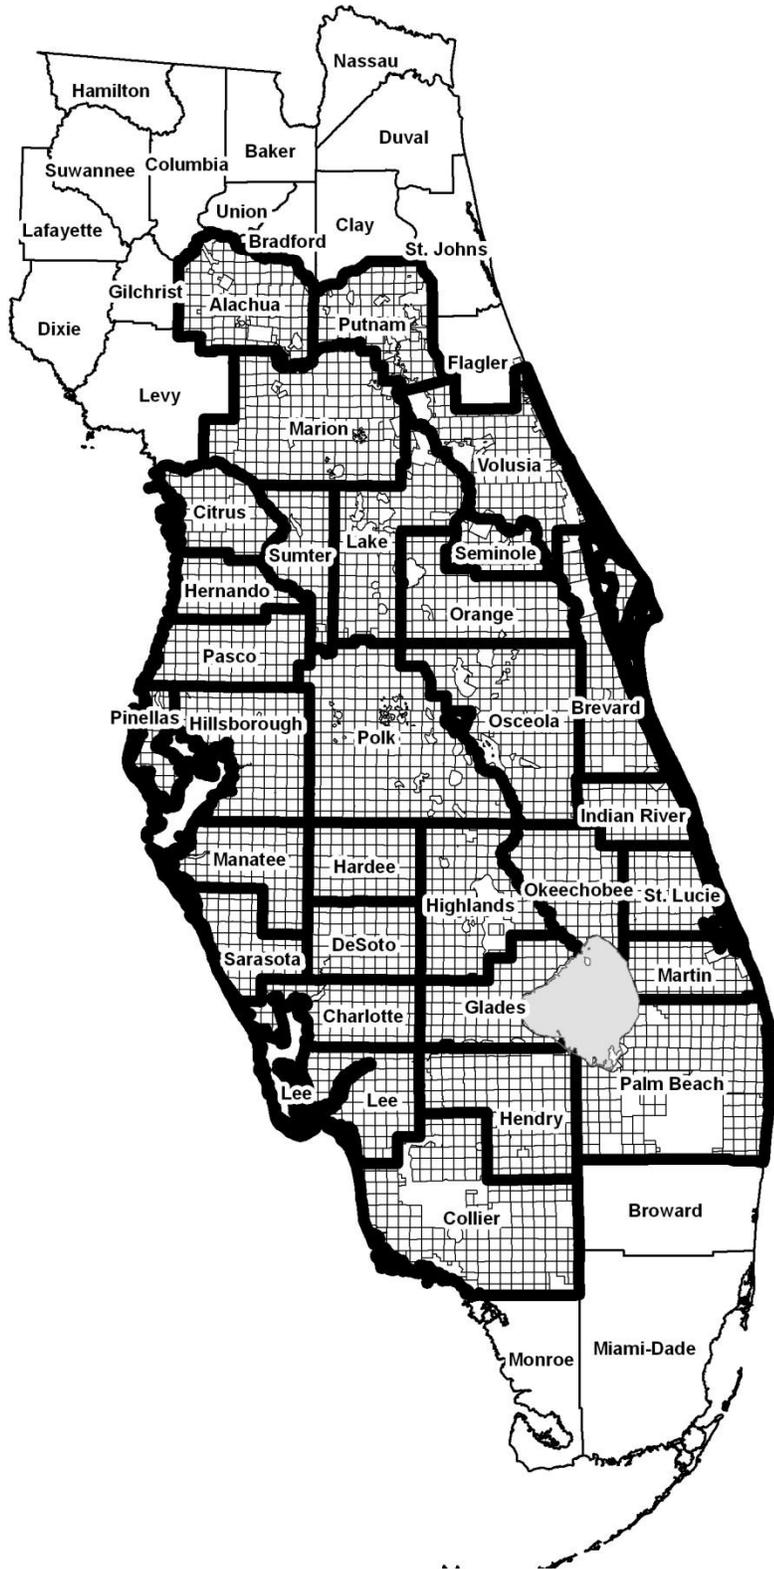

⁸ Includes tangelos.

World Citrus Production, by Selected Country: 2009-2010

Florida Public Land Survey System for Selected Citrus Producing Counties

Survey Procedures

This publication presents the results of the second annual survey of Florida citrus trees (following 22 biennial surveys) and is the fourth using digital imagery. The remotely sensed data allows for rapid replacement and maintenance of background images. Grove boundaries are digitized and saved as geodatabases in our GIS. The software provides additional tools to enhance comparative photo interpretation for grove change detection. Field checking of new and altered acreage follows. Changes detected on images and in field observations are used to update the previous inventory. This technology provides current tree inventory data for evaluating Florida's potential citrus production in a shorter period of time and at less cost than by ground survey methods alone.

The data in this report relate to commercial groves, those containing a minimum of 50 trees from which fruit is generally sold. In addition, the grove must have been cultivated and trees must show viable growth in the limb scaffold. Variety totals were rounded to the nearest acre and one hundred trees. All item totals that fell below these parameters were listed as zero. For this reason, users are cautioned that zero cells in the data tables could actually have a positive entry, but would be less than one half acre and below 50 trees.

The acreage shown is land which is actually planted with citrus trees. Bayheads, ponds, sinkholes, drainage canals, lateral and swale ditches, roads, turn rows, and wide middles were excluded. Where vacancies within a commercial grove were numerous, they were counted and acreage was then reduced to equivalent net acres of commercial trees. Non-bearing trees are listed by the calendar year in which set. Bearing trees are aggregated into three year groupings (except for the three oldest age groupings). When available, grove managers' records were used to establish age. Young tree age was estimated from both trunk circumference and tree height.

Identification of citrus varieties is generally dependent upon the presence of fruit. Many young groves visited for the first time are indexed as unidentified until fruit is available for variety determination. Acreage and trees in this report listed as "Unidentified" will be resurveyed and classified by variety in the next inventory. The unidentified trees and acres are listed by year set and by county under all Florida citrus. The unidentified trees and acres are also included in the all orange and all grapefruit totals.

Data itemized under "Other citrus" include minor types and varieties, such as K-Early Citrus, kumquats, limes, Ortaniques, Ponkans, pummelos, certain tangerines (Dancy, Robinson, and Satsuma), unclassified citrus, and unidentified mandarins. They are not reported individually or by year set within county due to lack of space.

The Florida Agricultural Statistics Service first began indexing citrus groves on aerial photography with the January 1966 survey. The 1966 inventory report included detailed data by county, variety, and year set; and the survey was designed for quick and economical updating. Subsequent surveys, using aerial photography, were conducted as of January every two years through 2008. Imagery covering every county has been acquired. Survey personnel received field kits containing a plot map of the digital imagery covering one quadrant of a township (9 sq. mi.) and printouts to assist in locating groves needing inspection.

On the computer, digital imagery layers can be turned on and off while working in a county file permitting comparison between different time periods. Photo interpreters identify all groves where new trees appear. These groves are then visited by ground crews. If field inspection finds a significant number of new trees, a count is made and the older trees or vacancies reduced accordingly. Based on this new count of trees, the acreage is recalculated for each record in the grove.

With the change to an annual survey came a systematic division of the workload. Florida land is divided into townships composed of 36 sections, each usually 1 square mile in area. In an odd-numbered year, those sections in the northern half of each township are visited. The sections in the southern half of the townships are visited during the even-numbered years. As time permits, additional grove inspections are performed during the survey period.

Field personnel identify varieties in blocks where trees were too young to be identified in earlier surveys, change the status of declining blocks, delineate new groves, and record new trees in existing groves. In blocks of citrus which are interset, acreage is proportionate to the number of trees of each variety or age in the block. In the multi-reset blocks, two or more resets are planted for each tree removed and the spacing must be averaged due to the variable distance between trees. The spacing between rows in one direction remains constant for grove travel. Field work is completed in mid-July.

Following field inspection, photo interpreters create polygons which are linked to datasets, and saved in county geodatabases for all new citrus groves. Changes in variety blocks may result in alterations to grove boundaries or status. A software tool provides the means to measure the exact acreage of new and altered citrus groves. All statistical information (identifying features, variety, year set, tree spacing, tree numbers, and vacancies) is then keyed into a database and retained for future use. Net acres are computed from the combination of tree numbers and tree spacings as measured by field personnel.

New maps are plotted and new section tabulations are printed to prepare updated field kits since resurveying is a continual process. Quality checks for accurate variety counts will be conducted as well as the identification of the three-year-old plantings that are to be included in next year's objective count surveys.

During the major portion of the survey, the Division of Plant Industry supplied trained citrus technologists with 4-wheel drive vehicles to work in conjunction with the tree inventory field inspection team.

Survey Highlights

Results of the annual commercial citrus inventory show a net decrease of 14,777 total citrus acres, or 3 percent from the last survey. The gross loss of 25,109 acres was larger and the new plantings of 10,332 acres were smaller compared to the previous inventory.

Since the year 2000, total acreage has declined 33 percent or 278,238 acres. The drop of nearly 12 percent of citrus trees since the 2006 tree inventory is a result of record cold temperatures, citrus canker, greening disease, and commercial development.

Of the 30 counties included in the annual citrus inventory, 23 recorded decreases and 7 showed increases in acreage. Martin County experienced the greatest loss in acreage at 4,386, while Palm Beach County had the highest percentage loss at 55 percent. Polk had the largest gain and continues to lead with the most acres at 83,471. Hendry is second with 66,814 acres while DeSoto and Highlands follow with over 62,000 acres each.

Total citrus trees are down 3 percent from 74,090,500 in 2009 to 72,164,800 in 2010. Hendry remains the leader with the most trees with over 10.0 million, followed closely by Polk less than 10.0 million, DeSoto with 8.3 million, and Highlands with 8.0 million trees. Of the total, oranges comprise 88 percent; grapefruit, 8 percent; and the remainder includes specialty and other citrus at 4 percent. Since 2009, bearing trees decreased 3 percent to 67,655,800 while non-bearing trees decreased by less than 1 percent to 4,509,000.

¹ January freezes in 1971, 1977, 1981, 1982, 1985, and 1986. December freezes in 1983, 1985, and 1989.

² August and September hurricanes in 2004, October hurricane in 2005.

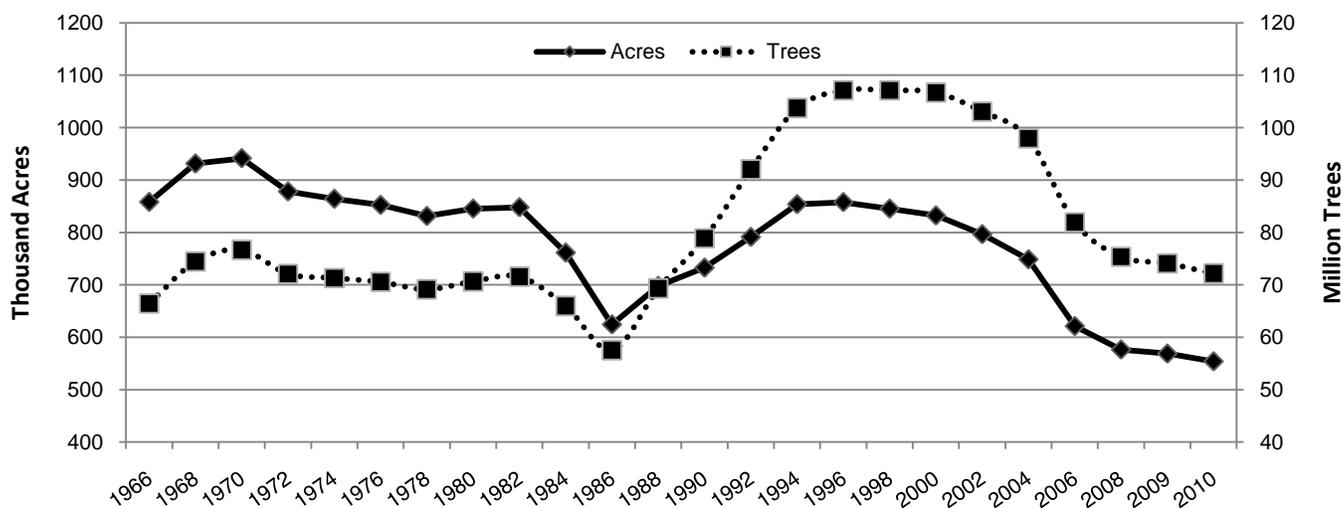

³ One year change beginning in 2009.

All Citrus: Number of Multiblocks (Groves), by Acreage and Survey Year

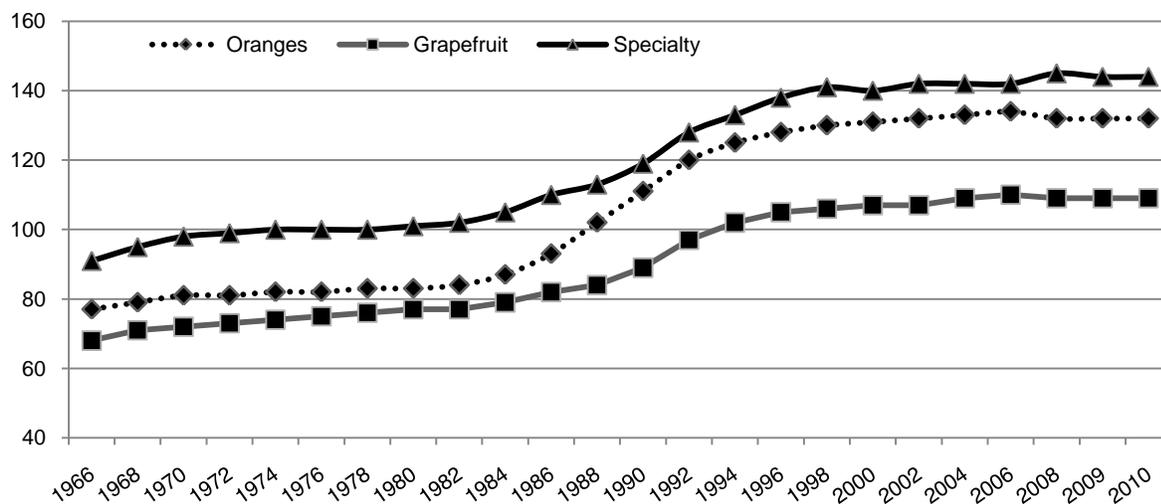

[A multiblock or grove for this table is a parcel of land, as determined by field personnel. The boundaries of the parcel are easily distinguishable by the field personnel. Within the boundaries is citrus with a homogenous planting scheme.]
