ACKNOWLEDGMENT

The inventory data contained in this report was developed at the request of and with funds provided by Florida's Citrus Industry. Its leaders sought accurate information for projecting future production and recognized the requirement to maintain citrus tree and acreage inventories on a current basis.

The work was directed by the Florida Agricultural Statistics Service which supervised photography, photo interpretation, field checking, and assembly of the data. Field survey work was a continuing cooperative project of the Florida Agricultural Statistics Service and the Division of Plant Industry.

Private and public officials contributed to this work by supplying information and other assistance. Many growers supplied basic data. These contributions are sincerely appreciated.

Public Land Survey System Florida Citrus Growing Areas

SURVEY HIGHLIGHTS

Total citrus acreage was reduced to 576,577 and is currently the lowest since record keeping began with the 1966 tree inventory. Since the year 2000, total acreage has declined nearly 31% or the equivalent of 255,698 acres. The drop of 7% since the 2006 tree inventory is a direct result of increased urban development, tree removals due to citrus canker and greening diseases, abandonment of non-productive groves, and two planned water reservoirs located in major citrus producing areas. Contributing to the reduction was the lack of citrus nurseries causing shortages of available new trees. Only 22,128 acres of new plantings occurred in 2008, the least since the 19,496 acres in 1972.

Acreage decreases were recorded in 25 of the 30 counties. One water management reservoir built on former agricultural land in Indiantown contributed to Martin County's loss of 34% or 11,869 citrus acres. Hendry County has the greatest amount of trees recorded at 10.6 million but lost 9,799 acres due to citrus canker and greening. Polk County has 81,375 acres, the most acreage of any county, along with 9.7 million trees. Hendry, Highlands, and DeSoto follow with over 60,000 acres each. Osceola and Hillsborough counties each have acreage losses of almost 25%. New plantings declined from 23,623 in 2006 to 22,128 acres in 2008.

All citrus trees are down 8.0% from 81,909,000 in 2006 to 75,376,100 in 2008. Of the total, oranges comprise 87%, grapefruit 8%, and the remainder includes specialty and other citrus. Since 2006, bearing trees decreased 7.2% to 71,000,600 while nonbearing trees declined 19.5% to 4,375,500.

The total inventory of acres by year set as recorded in the censuses of 1990 through 2008 is shown on page 13. The 2008 inventory indicates that only 229,008 acres (31.3%) remain from the 732,757 reported in the 1990 inventory. The gross decline in the past two years is 10.8% of the acres listed in the 2006 inventory. Gross loss of the orange acreage amounts to 10.1% while grapefruit shows a gross loss of 12.1%. Tangelos have suffered a gross loss of 15%. Early tangerines have a gross loss of 12.9% while Honey tangerines fared better with a loss of only 11.0%.

Due to Federal requirements to avoid disclosure, variety totals on pages 14-37 list the top 10 counties in acreage, followed by their corresponding tree numbers. Variety totals by Marketing District and detailed listings for the Florida SunRidge and Gulf as well as the Indian River Marketing District begin on page 40.

SURVEY PROCEDURES

This publication presents the results of the 22nd biennial survey of Florida citrus trees and is the second using digital imagery. The remotely sensed data allows for rapid replacement and maintenance of background images. Grove boundaries are digitized and saved as geodatabases in our GIS. The software provides additional tools to enhance comparative photo interpretation for grove change detection. Field checking of new and altered acreage follows. Changes detected on images and in field observations are used to update the previous inventory. This technology provides a current tree inventory data for evaluating Florida's potential citrus production in a shorter period of time and at less cost than by ground survey methods alone.

The data in this report relate to commercial groves, those containing a minimum of 50 trees from which fruit is generally sold. In addition, the grove must have been cultivated and trees must show viable growth in the limb scaffold. Variety totals were rounded to the nearest acre and one hundred trees. All item totals that fell below these parameters were listed as zero. For this reason, users are cautioned that zero cells in the data tables could actually have a positive entry, but would be less than one half acre and below 50 trees.

The acreage shown is land which is actually planted with citrus trees. Bayheads, ponds, sinkholes, drainage canals, lateral and swale ditches, roads, turn rows, and wide middles were excluded. Where vacancies within a commercial grove were numerous, they were counted and acreage was then reduced to equivalent net acres of commercial trees. Non-bearing trees are listed by the calendar "year in which set." Bearing trees are aggregated into three year groupings (except for the three oldest age groupings). When available, grove managers' records were used to establish age. Young tree age was estimated from both trunk circumference and tree height.

Identification of citrus varieties is generally dependent upon the presence of fruit. Many young groves visited for the first time are indexed as unidentified until fruit is available for variety determination. Acreage and trees in this report listed as "unidentified" will be resurveyed and classified by variety in the next census. The unidentified trees and acres are listed by year set and by county under all Florida citrus. They are also included in the all orange and all grapefruit totals.

Data itemized under the heading of other citrus include minor types and varieties, such as K-Early Citrus, kumquats, limes, Ortaniques, Ponkans, pummelos, certain tangerines (Dancy, Robinson, and Satsuma), unclassified Citrus, and unidentified mandarins. They are not reported individually or by year set within county due to lack of space.

The Florida Agricultural Statistics Service first began indexing citrus groves on aerial photography with the January 1966 survey. The 1966 inventory report included detailed data by county, variety, and year set; and the survey was designed for quick and economical updating. Subsequent surveys, using aerial photography, were conducted as of January every two

years through 2006. Imagery covering every county has been acquired. Survey personnel received field kits containing a plot map of the digital imagery covering one quadrant of a township (9 sq. mi.) and printouts to assist in locating groves needing inspection.

On the computer, digital imagery layers can be turned on and off while working in a county file permitting comparison between different time periods. Photo interpreters identify all groves where new trees appear. These groves are then visited by ground crews. If field inspection finds a significant number of new trees, a count is made and the older trees or vacancies reduced accordingly. Based on this new count of trees, the measured block acreage is then divided among the ages of trees.

In December 2007, field crews began ground checking sites that had been questioned by imagery interpreters. All blocks showing changes since the 2006 flight were visited. Crews also identified varieties in blocks where trees were too young to be identified in earlier surveys. In blocks of citrus which are interset, acreage is proportionate to the number of trees of each variety or age in the block. In the multi-reset blocks, two or more resets are planted for each tree removed and the spacing must be averaged due to the variable distance between trees. The spacing between rows in one direction remains constant for grove travel. Field work was completed the second week of July.

Following field inspection, photo interpreters create polygons which are linked to datasets, and saved in county geodatabases for all new citrus groves. Changes in variety blocks may result in alterations to grove boundaries or status. A software tool provides the means to measure the exact acreage of new and altered citrus groves. All statistical information (identifying features, variety, year set, tree spacing, tree numbers, and vacancies) is then keyed into a database and retained for future use. Net acres are computed from the combination of tree numbers and tree spacings as measured by field personnel.

New maps are plotted and new section tabulations are printed to prepare updated field kits since resurveying is a continual process. Quality checks for accurate variety counts will be conducted as well as the identification of the three year old plantings that are to be included in next year's objective count surveys.

During the major portion of the survey, the Division of Plant Industry supplied trained citrus technologists with 4-wheel drive vehicles to work in conjunction with the tree census field inspection team. Skilled assistance was also provided by personnel from the Division of Fruit and Vegetables upon completion of their inspection duties.
